William W. Olney[§]

November 28, 2022

Abstract

This paper examines gender differences among top US business executives using a large executive-employer matched data set spanning the last quarter century. Female executives make up 6% of the sample and exhibit more labor market churning – both higher entry and higher exit rates. Unconditionally, women earn 26% less than men, which decreases to 8% once executive characteristics, firm characteristics, and in particular job title are accounted for. We find that female executives are disproportionately represented in firms with more temporal flexibility and female-friendly corporate cultures, but this does not explain the gender pay gap. Rather, corporate culture is correlated with gender pay gaps within firms; specifically the within-firm gender pay gap is significantly smaller at female-friendly firms.

Keywords: Executive Compensation, Gender Pay Gap, Corporate Culture

1 Introduction

Convergence between men and women in terms of employment and compensation has been well documented, but this convergence is not complete and progress has not been uniform. For instance, women are underrepresented in the corporate business world and at the top of the income distribution more generally, where relatively large gender wage gaps remain (Blau and Kahn, 2017; Goldin, 2014; Guvenen et al., 2020).¹

This paper examines gender gaps in executive representation and compensation. By focusing on top business executives, we are studying an occupation where gender gaps are relatively large and a point in workers’ careers when these gaps tend to widen.² Thus, our analysis offers unique insights and broader lessons on potential impediments to female employment and pay equity. We expand on existing work by exploring the extent to which corporate culture and preferences for temporal flexibility can explain executive gender gaps in entry, exit, and compensation.

We utilize a large executive-firm matched data set covering publicly traded U.S. firms over the last quarter century. The dataset combines executive-level information from *ExecuComp* and firm-level information from *Compustat*, which both come from company filings with the Securities and Exchange Commission (SEC). We complement this with the *KLD Research and Analytics’* corporate social responsibility index, which has firm-level information on temporal flexibility and corporate culture.

Our analysis begins by examining the gender gap in executive employment. Women represent 6% of top business executives. The share of women has steadily increased over time, but it still remains low at 10% by the end of the sample period. This increase over time has been driven by higher entry rates for women compared to men.³ Interestingly, however, exit rates are also higher for women, which indicates there is more labor market churning for female executives. This suggests that, in addition to the promotion and recruitment of women, the retention of female executives is important.

Next, we examine how temporal flexibility and corporate culture relate to gender gaps in entry

¹This is not specific to the United States. See for example Albrecht et al. (2003) and Arulampalam et al. (2007).

²For example, Bertrand et al. (2010) find that the compensation of male and female MBAs is the same immediately after graduation but diverges thereafter.

³Entry occurs when the person becomes a new top 5 executive at a firm, and exit is when the person is no longer a top 5 executive at that firm.

and exit rates. To quantify temporal flexibility we utilize the *KLD* measure of whether the firm offers flextime benefits; to quantify corporate culture we use the *KLD* measure of firm diversity (the extent to which a firm has hired and promoted women and minorities in leadership positions) and whether the firm has ever had a female CEO.

Overall, temporal flexibility and female-friendly corporate culture are rare in this profession, which could explain the low numbers of female executives, especially if women value temporal flexibility more than men do or derive more disutility from competitive, male-dominated environments. Indeed, we find that female executives are disproportionately found in flexible and female-friendly firms. In addition, female entry rates are higher at flexible firms, and female exit rates are lower at female-friendly firms.

In addition to the gender employment gap, we also explore gender differences in compensation among these top business executives. Unconditionally, women earn 26% less than men. The pay gap falls to 15% after accounting for the characteristics of the executive (including experience, education, and age), and remains fairly constant after the addition of industry fixed effects, firm fixed effects, and a range of time-varying firm controls. The pay gap falls by about half after controlling for the job title of the executive. Accounting for all of these individual, firm, and job characteristics, we still find a conditional gender pay gap of about 8%. In other words, female executives with similar experience and education, working at similar firms, and doing similar jobs earn less than their male colleagues. We also find that the conditional pay gap has steadily decreased over our sample period.

Temporal flexibility and corporate culture may contribute to the gender pay gap in two ways. First, a compensating wage differential framework predicts that gender gaps can arise from women selecting into firms that provide these amenities and pay lower wages on average.⁴ While we do show that female executives tend to end up in firms offering temporal flexibility and a female-friendly corporate culture, this sorting of men and women across firms is not responsible for the gender pay gap. Specifically, the estimated pay gap remains stable across specifications that control for firm flexibility, firm culture, and also firm fixed effects.

Second, flexibility and corporate culture could generate gender pay gaps within firms: if women

⁴Goldin (2014), Goldin and Katz (2016), and Blau and Kahn (2017) make this argument with respect to temporal flexibility.

choose shorter or flexible hours and get paid less as a result, or if insider relationships and personal connections favor men within the firm. While we find little evidence that temporal flexibility explains within-firm gender pay gaps, corporate culture does play an important role. At female-friendly firms, the gender pay gap is much smaller. Specifically, firms that have had a female CEO and firms that have promoted gender and racial diversity compensate male and female executives similarly. Conversely, at firms that lack these features, a corporate culture disproportionately favoring men prevails, and the gender pay gap is larger. A back of the envelope calculation shows that about 18% of the decline in the conditional pay gap over the sample period can be explained by a more female-friendly corporate culture.

Finally, we examine whether the gender pay gap varies with the type of compensation. Compared to fixed compensation schemes (i.e. salary), discretionary pay is often more susceptible to the influence of negotiation, personal connections, and insider relationships which could disproportionately favor men (Biasi and Sarsons, 2020; Cullen and Perez-Truglia, 2019; Keller and Olney, 2021). Our findings show that the gender gap is larger for non-salary forms of compensation, such as bonuses. However, this gender gap in discretionary pay is substantially smaller at female-friendly firms. These findings provide additional evidence that a male-dominated corporate culture is contributing to the gender pay gap.

Our paper builds on the existing work examining gender differences among top business executives (Albanesi and Olivetti, 2006; Bell, 2005; Bertrand and Hallock, 2001; Gayle et al., 2012). These studies typically focus on whether gender pay gaps can be explained by differences in individual characteristics (Bertrand and Hallock, 2001; Gayle et al., 2012) or by differences in firm performance (Albanesi and Olivetti, 2006), while we focus on the role that temporal flexibility and corporate culture might play – not only with respect to the gender pay gap, but also when it comes to gender differences in entry and exit. Furthermore, our much larger dataset is especially appealing when studying the relatively small number of women in this profession. Our novel approach and appealing data has led to three key contributions.

First, we show that female exit is an important reason for the low female share in this occupation. Several studies highlight the importance of gender gaps in *promotion* in various settings (Bronson and Thoursie, 2020; Lundberg and Stearns, 2019), but our findings highlight the need to better understand the *exit* decision. Interestingly, we find that gender gaps in exit are smaller at female-

friendly firms. Thus, the higher female representation at firms with female leadership, which we document and which is consistent with Bell (2005) and Matsa and Miller (2011), could be due to these firms improving female retention, as opposed to increasing female entry.

Second, this paper contributes to our understanding of the role that selection and compensating wage differentials play in determining gender pay gaps. Although the literature has found women sorting into low-paying firms to be an important driver of gender pay gaps primarily for lower-skilled women (Card et al., 2016; Casarico and Lattanzio, 2020), we focus on the other end of the skill distribution and find little evidence for this. For example, we show that female executives seem to value temporal flexibility, consistent with existing work (Goldin and Katz, 2016; Hotz et al., 2018; Mas and Pallais, 2017; Wiswall and Zafar, 2018), but we find no evidence that sorting along this dimension contributes to the gender pay gap. Although female executives do end up in more flexible and female-friendly firms, our results show they do not pay for their preference for these amenities in the form of lower compensation, as would be predicted by a compensating wage differential framework.

Finally, our results indicate that corporate culture is an important determinant of gender gaps within firms. Smaller gender pay gaps at female-friendly firms is consistent with evidence that female leadership is associated with reductions in the gender pay gap (Bell, 2005; Kunze and Miller, 2017; Matsa and Miller, 2011; Tate and Yang, 2015). We expand on this evidence by exploring the role that firm diversity and temporal flexibility play in explaining within-firm gender pay gaps (the former is important while the latter is not), as well as gender gaps in entry and exit. Overall, our findings indicate that female-friendly firms mitigate the effects of corporate culture on gender employment and pay gaps.

In the next section, we outline the data sources used in our analysis and provide some descriptive evidence on gender differences in this profession. Section 3 describes the empirical strategy used to examine gender gaps in executive employment and compensation. We present our results in section 4, where we examine the low female share in our sample, gender gaps in entry and exit, and the role of temporal flexibility and corporate culture. Our attention then shifts to gender gaps in compensation in section 5, where we focus on how temporal flexibility and corporate culture affect across-firm and within-firm gender pay gaps. Finally, section 6 provides some concluding thoughts.

2 Data

We construct an executive-firm matched data set that incorporates detailed data on compensation, executive characteristics, and firm characteristics. In this section, we describe our various data sources and then report summary statistics on gender differences.

2.1 Executive Information

Information on executive compensation is obtained from the *Compustat ExecuComp* data set, which is based on filings with the U.S. Securities and Exchange Commission (SEC). This is the most comprehensive publicly available data set on executives and covers the top executives within each Standard & Poor (S&P) firm. We include in our analysis the top five highest paid executives for each firm in each year.⁵ Our measure of executive compensation is *ExecuComp's* TDC1, which includes total compensation awarded to an executive in a given year. Results are similar using an alternative measure, TDC2, which captures compensation realized by an executive in a given year. All nominal compensation values are converted to 2017 U.S. dollars using the Consumer Price Index (CPI) provided by the Bureau of Labor Statistics.

Importantly, the *ExecuComp* data set identifies the gender of the executive, which allows us to measure the share of female executives as well as the gender pay gap. We account for other executive characteristics in the analysis, including experience, education, and age. Experience is defined as the number of years the individual has been a top five executive at any firm in the *ExecuComp* data set.⁶ Education is defined as whether the executive has a doctorate degree. Binary variables indicating the age decade of the executive (i.e. thirties, forties, etc.) are also included as controls in our analysis.⁷

While our analysis focuses on top business executives, individuals within this labor market are likely performing different types of tasks, which could influence compensation. The occupation of the executive is identified using the ‘title’ variable in the *ExecuComp* data set. We focus on the

⁵The SEC requires firms to report compensation information for their top five executives but some firms report more. The average number of executives reported changes over time which could influence the evolution of the female share and the gender pay gap. Thus, we drop non-top five executives from our sample.

⁶Results are similar if we measure experience as the number of years the individual has been a top five executive at a particular firm.

⁷We include a dummy for missing age to maintain the sample size in light of incomplete information for some executives.

following five job titles: ‘CEO and Chair’, ‘Vice-Chair’, ‘President’, ‘Chief Financial Officer (CFO)’, and ‘Chief Operating Officer (COO)’ which we rank according the literature’s assessment of their prestige (Albanesi and Olivetti, 2006; Bertrand and Hallock, 2001).⁸ This allows us to examine whether the gender composition differs across these job titles, and it provides an opportunity to account for the tasks performed by the executive when measuring gender pay gaps.

An appealing feature of the data is that we can follow executives over time, which allows us to construct measures of executive entry and exit. Entry is a binary variable equal to one if an individual became a new top 5 executive at that particular firm in a given year. Exit is a binary variable equal to one in the last year an executive was a top 5 executive at the firm. We are interested in whether entry and exit rates differ for men and women. This will provide an opportunity to examine how entry and exit contributes to the gender gap in executive representation, and offers insights into which firms are better at attracting, promoting, and retaining female executives.⁹

2.2 Firm Information

Executive compensation information from the *ExecuComp* data set is linked to company-level measures in *Compustat* using a unique firm identifier, which allows us to construct an executive-firm matched data set. This provides an opportunity to examine whether firm characteristics influence the gender gap within this labor market. Firm size, measured using sales, may influence executive composition and compensation. We also account for firm markups, which have been steadily increasing since 1980 (De Loecker et al., 2020).¹⁰ We anticipate that firm performance last year (i.e. sales and markups) could influence executive turnover or compensation this year. A measure of insider board relationships is also included, which is defined as a binary variable indicating whether three or more executives serve on the board of directors. We expect that executives will earn more at firms with this type of insider board structure. Finally, we identify

⁸These job titles are mutually exclusive definitions which are constructed by searching for substrings within *ExecuComp*’s title variable. For instance, the following non-case sensitive titles ‘CEO’, ‘Chief Executive Officer’, ‘Chairman’, ‘Chmn.’, and ‘Chair’ are included in our ‘CEO and Chair’ job title definition.

⁹In the data we can see the executive enter (or leave) the sample of top 5 executives at the firm, but we do not observe if she was promoted from within the firm or arrived from another firm outside our sample. There are relatively few instances of executives switching from one firm in the *Execu Comp* data to another firm (Keller and Olney, 2021). Specifically, 92% of executives in our data set work at only one firm. Note that executives with gaps in their tenure at the firm are not classified as entering or exiting because the executive may simply have moved in or out of the top five at the firm.

¹⁰Using *Compustat* data, firm-specific markups are calculated as $0.85 \times (\text{total sales} / \text{total costs of goods sold})$ following De Loecker et al. (2020).

the firm’s main six-digit NAICS industry using the Compustat dataset.

Our firm-level measures of temporal flexibility and corporate culture come from *KLD Research and Analytics*, a source commonly used in economics and finance research (Cronqvist and Yu, 2017). Ninety percent of the Compustat sample is matched to the *KLD* data using a unique firm ticker variable. We use the *KLD* data to identify whether the firm offers temporal flexibility to its workers. Specifically, a binary *KLD* variable identifies whether the firm has “outstanding employee benefits or other programs addressing work/life concerns, e.g., childcare, elder care, or flextime” (called “Div_str_d” in the *KLD* dataset). In our main analysis, we take the firm-level average of this variable over the available years to maintain our sample size in light of *KLD* data constraints (i.e. missing values increase post-2009).¹¹ Our results, however, are robust to the use of time-varying *KLD* measures, despite a much smaller sample size (See Appendix Table A5).

We measure corporate culture using *KLD* data on whether the firm has hired and promoted women and minorities in leadership positions. Specifically, we use binary *KLD* variables indicating whether the firm has a CEO who “is a woman or a member of a minority group” (Div_str_a), “has made notable progress in the promotion of women and minorities, particularly in line positions with profit and loss responsibilities” (Div_str_b), and has “strong gender diversity on their board of directors” (Div_str_c). We calculate the average of these three measures and then take the firm-level average over the available years. Finally, using the *ExecuComp* data we construct another measure of female-friendly corporate culture that identifies whether the firm has ever had a female CEO. Together these measures will provide new insight into whether gender employment and pay gaps are affected by temporal flexibility or corporate culture within the firm.

2.3 Summary Statistics

This section documents gender differences in the market for top business executives. Our sample consists of almost 240,000 observations and spans 26 years (1992-2017), about 3,500 firms, and 45,000 executives. The sample is over five times larger than existing studies of gender gaps among top business executives, which is important when studying an occupation where there are relatively few women.¹² Average total compensation in this sample (in 2017 dollars) is \$3.96 million, and

¹¹Using time-invariant measures has the added benefit of avoiding potentially endogenous changes over time within the firm, which reduces reverse causality concerns.

¹²See for example Bertrand and Hallock (2001) and Albanesi and Olivetti (2006).

median compensation is \$1.97 million.

Table 1 reports summary statistics of our key variables for men and women separately, along with the differences between the two. A comparison of the number of male and female observations indicates that women comprise 6.2% of our sample. For male executives the mean natural log of total compensation is 7.43. In contrast, women earn 17 log points (approximately 16%) less than men, and this difference is statistically significant. In fact, there are statistically significant gender differences in all variables summarized in this table. Men have more experience (5.6 versus 5 years), are more likely to hold a doctorate (0.02 versus 0.01), and are on average older (52.5 versus 50 years old). Firms which employ female executives tend to have lower sales and higher markups, and men are more likely to be at firms that have insider board relationships.

While the overall share of female executives is 6.2%, there is substantial variation in this female share across job titles. For instance, Appendix Figure A1 shows that only 2.7% of CEOs in our sample are women. However, 4.8% of Presidents are women and 7.9% of CFOs are women. Overall, we see that the share of women typically falls as the job becomes more prestigious. Not only are women underrepresented overall in this profession, an even smaller share rise to the top leadership positions. The share of women is relatively high (8%) in “other” executive positions, with less prestige and potentially more temporal flexibility.

In Appendix Figure A2, we explore how the share of women varies across age cohorts: female shares are much larger among younger cohorts. This pattern could reflect that women are less likely to become CEOs (see Figure A1) and thus they exit this labor market. Alternately, perhaps fewer women historically were able to join the track towards top leadership positions and thus there are now fewer women among this older cohort.

Finally, Appendix Table A1 reports summary statistics of our corporate culture and flexibility variables of interest, and how these measures vary across firm type. Nine percent (322 of the 3,456 firms) have had a female CEO in at least one year of the sample, while 37 percent (1291 firms) are diverse and 6 percent (277 firms) are flexible (defined as having non-zero diversity and flexibility scores, respectively). Furthermore, average diversity and flexibility scores have approximately doubled from the beginning of the sample to the last year of available data, while the share of firms with female CEOs has increased even more dramatically – from less than a percent in 1992 to 6.8% in 2017.

Table 1: Summary Statistics

	(1)	(2)	(3)
	Males	Females	Difference
Total Comp	7.430 (1.058)	7.261 (0.991)	-0.169*** (0.009)
Salary Comp	6.122 (0.693)	5.996 (0.612)	-0.126*** (0.005)
Non-Salary Comp	6.871 (1.575)	6.727 (1.447)	-0.144*** (0.012)
Experience	5.640 (4.299)	4.972 (3.761)	-0.668*** (0.033)
Dr.	0.020 (0.141)	0.011 (0.104)	-0.009*** (0.001)

CEO/Chair	0.250 (0.433)	0.105 (0.307)	-0.145*** (0.003)
Vice Chair	0.018 (0.132)	0.012 (0.108)	-0.006*** (0.001)
President	0.121 (0.326)	0.093 (0.291)	-0.027*** (0.003)
COO	0.033 (0.179)	0.027 (0.163)	-0.006*** (0.001)
CFO	0.140 (0.347)	0.185 (0.389)	0.045*** (0.003)
Other Title	0.438 (0.496)	0.577 (0.494)	0.139*** (0.004)
Sales	21.196 (1.717)	21.158 (1.744)	-0.038** (0.016)
Markups	0.964 (0.431)	0.991 (0.440)	0.027*** (0.004)
Insider	0.170 (0.376)	0.105 (0.306)	-0.065*** (0.003)
Observations	219948	14477	234425

Notes: Sample consists of the top five highest paid executives for each firm in the *ExecuComp* dataset from 1992-2017. Standard deviations (in columns 1 and 2) and standard errors (in column 3) reported in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Compensation and sales are reported in logs (of 2017 dollars). Markups are equal to $\ln(0.85(\text{total sales} / \text{total costs}))$.

3 Empirical Strategy

3.1 Gender Gaps

The goal of our empirical analysis is to document and understand the executive gender gaps in employment and compensation. We begin by investigating whether the changes in the female employment share can be explained by gender differences in entry or exit rates. Specifically, the following estimating equation is used:

$$Y_{ijfnt} = \beta_1 Female_i + \beta_2 X_{1it} + \beta_3 X_{2fnt} + \gamma_t + \delta_j + \nu_n + \alpha_f + \epsilon_{ijfnt}, \quad (1)$$

where Y_{ijfnt} either represents entry or exit of executive i , with job title j , at firm f , in industry n , and in year t . As described above, we generate entry and exit variables to indicate when an executive enters or leaves the sample of top executives at the firm. In these regressions, β_1 identifies whether the female entry (or exit) rate is larger than the male entry (or exit) rate.

We rely on a similar specification to estimate the gender compensation gap. Specifically, log compensation is used as our dependent variable (Y_{ijfnt}) in equation 1. We begin with a basic specification that only includes the female indicator ($Female_i$) and year fixed effects (γ_t). The following controls are then sequentially added: individual controls for age, education, and experience (X_{1it}), industry fixed effects (ν_n), firm fixed effects (α_f), time-varying firm controls (X_{2fnt} , which include lagged sales and markups, as well as a dummy for insider board structure), and finally job title fixed effects (δ_j). Documenting how our estimates of β_1 change with the inclusion of these controls will shed light on how much of the raw pay gap can be explained by these factors.

3.2 Temporal Flexibility and Corporate Culture

Our analysis then examines the extent to which temporal flexibility and corporate culture explain the gender gaps in employment and compensation. We distinguish between how these explanations may lead to sorting across firms and how these explanations can also have within-firm effects.

Women may value temporal flexibility more than men do (Goldin and Katz, 2016; Hotz et al., 2018; Mas and Pallais, 2017; Wiswall and Zafar, 2018) and may derive disutility from a male-dominated environment (Hunt, 2016; Husain et al., 2018; Lordan and Pischke, 2016; Usui, 2008).

This could result in women gravitating towards firms with the amenities of flexibility and a female-friendly corporate culture. Our analysis will start by examining whether the share of female executives is higher at firms with these characteristics. To the extent that it is, we are then interested in whether this occurs because of higher female entry rates or lower female exit rates at firms with these amenities. We test this prediction using the following specification.

$$Y_{ijfnt} = \beta_1 Female_i + \beta_{flex} Female_i Flex_f + \beta_{div} Female_i Div_f + \beta_{ceo} Female_i FCEO_f + \beta_2 X_{1it} + \beta_3 X_{2fnt} + \gamma_t + \delta_j + \nu_n + \alpha_f + \epsilon_{ijfnt}. \quad (2)$$

where Y_{ijfnt} again is either entry, exit, or compensation of executive i , and we include the same set of controls and fixed effects. Here, $Flex_f$ is the firm-level flexibility variable from the KLD dataset, Div_f is the firm diversity index from the KLD dataset, and $FCEO_f$ indicates whether the firm has ever had a female CEO.

The sorting of executives into flexible and female-friendly firms can influence not only female shares but also the gender pay gap. A compensating wage differential framework predicts that firms that offer these amenities may pay less on average. According to this hypothesis, women select into these firms, their compensation is lower, and this leads to a gender pay gap. Estimating Equation 1 (with log compensation as the dependent variable and various firm controls) can help shed light on this. If compensating wage differentials are important, then controlling for temporal flexibility and corporate culture (and firm fixed effects) should reduce the estimated gender pay gap.

Second, flexibility and corporate culture can lead to gender pay gaps *within* the firm rather than *across* firms. For example, at firms where temporal flexibility is offered, women may choose shorter or flexible hours which are accompanied by less generous compensation. This would lead to a larger gender pay gap within flexible firms. Alternatively, more competitive and male-dominated firms may disproportionately disadvantage female executives, which would lead to smaller gender pay gaps in female-friendly firms. These predictions are tested by estimating Equation 2 using compensation as the dependent variable. If women are being paid less for taking more flexible hours, then there should be a larger gender gap at firms that offer this amenity (i.e. a negative β_{flex} coefficient). Conversely, there should be smaller gender gaps at firms with a more female-

friendly culture (i.e. positive β_{div} and β_{ceo} coefficients).

In each of the next two sections, we begin with some descriptive evidence on the gender employment and pay gaps, respectively, followed by the results of the regression analysis described above.

4 Gender Employment Gaps

Figure 1: Female Share of Top Executives over Time

We begin by documenting the gender gap in executive employment. As previously noted, the share of female executives in our sample is 6.2%. As we see in Figure 1, the female share has risen from 1.5% in 1992 to 10.1% in 2017.¹³ While the share of women still remains low in an absolute sense, these increases are substantial in relative terms. This section explores how this might be driven by gender gaps in entry and exit, and the extent to which temporal flexibility and corporate culture are playing a role.

¹³We show in Appendix Figure A3, however, that the increase documented here has been much slower in CEO or Chair positions relative to all other job titles.

4.1 Entry and Exit

An appealing feature of our data is that we can track executives over time and identify when they enter or exit a firm as a top five executive. We investigate whether differences in entry and exit rates for men and women can explain the low but rising female share of executives.

Figure 2: Entry and Exit

A. Female Shares: Entrants, Exiters, and Incumbents

B. Entry and Exit Rates by Gender

Notes: Panel A illustrates the female share of executives entering a top 5 position at a firm, the female share of executives exiting a top 5 position at a firm, and the female share of incumbent executives. Panel B reports the share of female entrants (and exiters) relative to all female executives and the share of male entrants (and exiters) relative to all male executives.

We begin by calculating the female share among newly entering executives, the female share among executives that exit a firm, and the female share among incumbent executives. We document the evolution of these shares over time in panel A of Figure 2. The findings show that the female share is higher among entrants than incumbents. However, the female share of exiters is also higher than incumbents throughout the sample period, which indicates that there is more labor market churning among female business executives. Note that the female share of entrants exceeds the female share of exiters throughout the sample period, which is consistent with the increasing female share of executives over time (see Figure 1). The higher female share among exiters than incumbents means that the overall female share of executives is not increasing as fast as entry alone would indicate.

Another approach is to calculate the entry and exit rates for men and women, as we do in panel B of Figure 2. The female (male) entry rate is the ratio of female (male) entrants compared to all female (male) executives, and the exit rates are calculated in an analogous way. Consistent with

the findings in panel A, both exit and entry rates are higher for women than men. Furthermore, the gender gap in entry rates is larger than the gender gap in exit rates.

As the regression analog of this exercise, we estimate Equation (1) using entry and exit as the dependent variables. The results in column 1 of Table 2 confirm that the female entry rate is higher. Specifically, the female entry rate is 8.5 percentage points higher than the male entry rate. However, in column 2 we find that the female exit rate is also higher: 3.6 percentage points higher than the male exit rate. The female coefficients in columns 1 and 2 are consistent with the gender gaps in entry and exit depicted in panel B of Figure 2. In columns 3 and 4, we show the significant positive coefficients are robust to the inclusion of executive controls, firm characteristics and fixed effects, and job title fixed effects, although the magnitude of both coefficients are smaller.¹⁴

Overall, these results show there is more labor market churning among female executives. The female entry rate is higher compared to men, but the female exit rate is also higher. Note that the vast majority of entry and exit we document is coming from brand new entrants into or complete exits from the sample of top executives at SP 500 firms - only 8% of executives in our sample ever switch firms within the dataset. While we cannot identify where the newly entering top executives are coming from (i.e. promoted from within the firm or recruited from another firm outside the dataset), or where the exiters are going (i.e. to another firm or leaving the labor force altogether), our findings nonetheless have important implications. Firms are recruiting and promoting more women into these top occupations each year, but they also appear to be less effective at retaining female executives.

4.2 Temporal Flexibility and Corporate Culture

We now examine whether characteristics of the firm are related to the gender gap in executive employment. As described in section 3, if women derive disutility from a male-dominated corporate culture, they might sort into firms with more female-friendly cultures. Similarly, if women value temporal flexibility more than men do, they will select into flexible firms.

As a first test of this hypothesis, we report the share of female executives at these different types of firms. Figure 3 supports the idea that men and women differentially sort across firms with

¹⁴In Appendix Table A2, we show that the large reduction in the female coefficient in the entry regression results primarily from the inclusion of age and experience controls (older and more experienced people are less likely to enter, and women tend to be younger and less experienced).

Table 2: Entry and Exit

these amenities. Panel A shows women are indeed much more likely to be at firms that have had a female CEO at least once in the study period. Specifically, the female share of executives at these firms is 16.2% while it is only 3.3% at all other firms.¹⁵ Because part of this could be mechanical (due to the presence of a female CEO at these firms), we also report these shares separately for each job title in panel B. Shares of Vice Chairs, Presidents, CFOs, COOs, and “Other” positions are all higher in female CEO firms than the remaining firm categories.

Figure 3 also shows the share of female executives is higher at diverse firms (9.0%), defined as those with a non-zero diversity score, than “Other” firms. Finally, the female share of executives is higher at firms that offer temporal flexibility in the form of childcare, elder care, and flextime (6.6%). These patterns hold for each individual job title (panel B). Overall, these findings suggest that women are sorting into firms that offer temporal flexibility and a female-friendly corporate culture and/or these firms are better at promoting women into leadership positions.

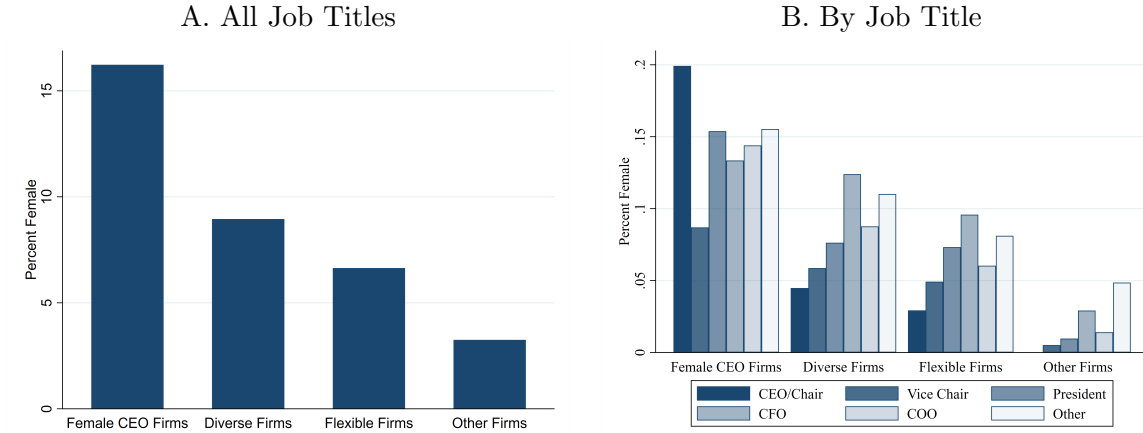

Alternatively, perhaps firms with high female executive shares end up becoming more diverse, flexible, and more likely to have a female CEO. To address this concern, we check whether female shares are indeed responding to firm characteristics (and not the other way around), by focusing on the five years before and after firms get their first female CEO, receive their first positive diversity score, or receive their first positive flexibility score. Panel A of Appendix Figure A5 shows that the female share (excluding women that are ever CEO) increases in the year after the firm’s first female CEO takes charge. This indicates that after a woman becomes CEO, the share of other female executives at the firm rises, which suggests a causal relationship and also indicates the findings are not driven by a mechanical relationship where the female CEO herself increases the female share of executives at the firm. Panel B shows overall female shares increase after the firm becomes diverse. In both panels, the female shares remain higher than the baseline year for at least five years. In short, female employment does appear to be responding to firm characteristics.¹⁶

Having established that the female share of executives varies by firm type, we now examine whether this is driven primarily by exit or entry. Specifically, we estimate equation (2), where entry and exit are regressed on the female binary variable and the interactions between this female variable and the temporal flexibility and female-friendly corporate culture measures.

¹⁵ “Other” firms are defined as those that have never had a female CEO, never promoted diversity, and never offered temporal flexibility.

¹⁶ The patterns for firm flexibility are less clear in panel C.

Figure 3: Share of Female Execs by Firm Type

Notes: Share of female executives at firms that have ever had a female CEO, at firms that promote diversity (non-zero diversity score), at firms that offer temporal flexibility (non-zero flexibility score), and at all other firms.

In Table 3, the coefficient on the interaction with our first corporate culture variable (female CEO) is insignificant in the entry regression (column 1), but negative and significant in the exit regression (column 2). The point estimate on the interaction term in column 2 is similar in magnitude to the female coefficient itself, which means that although exit rates are higher among women than men overall, at firms that have ever had a female CEO, this gap is almost non-existent.

Examining our next corporate culture variable (firm diversity), we find, somewhat surprisingly, that the female-male entry difference is smaller at diverse firms.¹⁷ However, consistent with our previous results, the negative interaction in column 2 indicates that the female exit rate is smaller at firms that prioritize diversity.

Finally we turn to temporal flexibility. Column 1 shows that female executives not only have higher entry rates overall (female coefficient of 0.03) but they are even more likely to join firms that provide temporal flexibility (female-flexibility interaction coefficient of 0.02). On the other hand, in column 2 there is no evidence that women are more or less likely to exit firms that provide flexibility.

In columns 1 and 2 of Appendix Table A3, we show that our results are robust to the inclusion of two additional sets of interactions: individual controls interacted with our three firm variables,

¹⁷One potential explanation is that diverse firms may be especially successful at recruiting and promoting minority men.

Regressions restrict to firms with non-missing flexibility and corporate culture variables.

and the female indicator interacted with firm characteristics (markups, sales, and insider board structure). These specifications allow firms to have differential effects on the entry and exit of workers based on their age, experience, and job title, and also ensures that the interactions of the female indicator with female-friendly firm characteristics are not picking up gender differences driven by other (potentially correlated) firm characteristics. In addition, to address the fact that there might be a mechanical relationship between the female CEO variable and female entry and exit, we drop CEOs entirely in columns 3 and 4 of Table A3. We still find that relative exit rates of women are lower at female friendly firms, and that relative entry rates are higher at flexible firms.

Overall these findings indicate that the higher share of women at female-friendly and flexible firms (see Figure 3) occurs for different reasons. Female-friendly firms have lower relative exit rates, while firms with temporal flexibility have higher relative entry rates. Thus, flexible firms are relatively better at encouraging the entry of female executives (via internal promotion or external recruitment), while female friendly firms are relatively better at retaining female executives.

5 Gender Pay Gaps

With a better understanding of the gender employment gap, our focus now shifts to the gender pay gap. First, we are interested in whether women’s lower compensation, seen in Table 1, can be explained by observable worker, firm, or job characteristics. Second, to the extent that a conditional gender pay gap does exist, we are interested whether this is due to sorting of male and female executives across firms with different amenities, or whether temporal flexibility and corporate culture lead to gender pay gaps within firms.

5.1 Conditional Gender Pay Gap

Our analysis begins with the estimation of Equation (1) using log total compensation as our dependent variable. The results show that the “unconditional” gender pay gap (after controlling for only year fixed effects) is -0.26 in column 1 of Table 4.¹⁸ This coefficient indicates that women earn approximately 26% less than men, when not accounting for any worker or firm characteristics.

¹⁸This point estimate is slightly larger than the raw difference in male and female compensation reported in Table 1 because both executive compensation and the share of female executives has been increasing over time.

Table 4: Gender Compensation Gap

Firm FE	No	No	No	Yes	Yes	Yes

Notes: Standard errors (clustered at the industry level) in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Columns 2 through 6 also control for a dummy for missing age. Sales and Markups are lagged one year.

Female and male executives differ along a number of dimensions, including experience, education, age, and job titles (see Table 1). In the remaining columns of Table 4, we examine the extent to which these observable differences between men and women can explain the unconditional pay gap found in column 1. We sequentially control for a variety of executive and firm characteristics that may influence compensation. For instance, controlling for age, experience, and education decreases the gender pay gap by eleven percentage points to 15% (column 2). Female executives tend to be young (Table 1), and these regression results show that executives in their forties, fifties, and sixties are paid increasingly more than those younger than 40 (the omitted category). More experienced executives earn more, while having a doctorate does not have a significant effect on compensation. In sum, while there exists a substantial unconditional gender pay gap among top executives, 40% of this gap can be explained by these individual worker characteristics.

Next we examine the role of industries and firm characteristics in explaining the remaining gender pay gap. If men and women select into industries and firms with different compensation structures, this could influence the gender pay gap. To test for this possibility, column 3 adds industry fixed effects in order to estimate the gender pay gap based on within-industry comparisons. Interestingly, the estimated gender pay gap barely changes, which suggests that differential sorting at the industry level is not an important explanation for the pay gap we document. Similarly, the next two columns show that firm characteristics do not appear to be driving the gender pay gap either. Controlling for firm fixed effects (in column 4) and also our time-varying firm characteristics (in column 5) both have a negligible effect on the gender pay gap. The female point estimate varies between 15-17% in columns 2-5. Thus, selection into particular industries or firms, does not play a major role in explaining the gender pay gap.

Occupations, on the other hand, do have an important impact on the gender pay gap. In column 6, we add indicators for each of the five top leadership positions: CEO/Chair, Vice Chair, President, CFO, and COO. All five positions earn more than the omitted ‘other’ category, and not surprisingly it is CEOs that earn the most. Controlling for job title also reveals that the monotonically increasing relationship between age and compensation documented in previous columns was driven in part by older executives being more likely to be in a top leadership position. In fact, after controlling for title, we see that compensation peaks around age fifty and then tails off for older executives. Importantly, we find that accounting for job title explains half of the remaining gender pay gap (the

female point estimate drops from -0.165 in column 5 to -0.079 in column 6).¹⁹ However, women still earn 7.9% less than men, after accounting for executive, firm, and job characteristics. In other words, female executives with similar experience and education, working at similar firms, and doing similar jobs earn less than their male colleagues.²⁰

Comparing our results to the existing literature, the finding that experience and occupation explain a sizeable portion of the gender pay gap is consistent with Blau and Kahn (2017). However, unlike Blau and Kahn (2017), we do not find that the industry explains much of the gender pay gap among top business executives, perhaps because compensation in this unique high-skilled labor market is not industry specific. In addition, our finding that the inclusion of firm fixed effects does not substantially alter our estimates of the gender gap suggests that sorting into specific firms is not an important driver of gender pay gaps in our setting, while other studies have found sorting to play a bigger role for lower-skilled workers (Card et al., 2016; Casarico and Lattanzio, 2020).

Like the share of female executives, the gender pay gap varies across age cohorts and has changed over our sample period. Appendix Figure A4 shows the conditional gender pay gap is much larger for executives in their thirties than it is for other age brackets. One potential explanation is that women in their thirties may be disproportionately affected by the time constraints associated with young children. This is consistent with evidence of a “child penalty” in compensation for women but not for men (Cortés and Pan, 2020; Keller and Utar, 2022; Kleven et al., 2019).

Illustrating changes over time, panel A of Figure 4 shows that compensation has increased (in real terms) for both men and women, while the gap between male and female earnings appears to have decreased. This can be seen more clearly in panel B of Figure 4, where the solid line plots the difference between male and female earnings. The unconditional pay gap declines by about half over this period, from about -0.4 in 1992 to about -0.2 in 2017. Interestingly, much of this decline took place in the first half of the study period, after which the series flattens out slightly.

We also report in panel B the evolution of the conditional gender pay gap. We find that in 1992 women earned about 20% less than similar male colleagues performing the same job. However, by 2017 female executives earned only 0.5% less than similar male colleagues. Unlike the unconditional

¹⁹This decline suggests that women lag behind men in promotion to the highest-paying positions, which has also been found in previous work (Bronson and Thoursie, 2020; Gorman and Kmec, 2009).

²⁰In Appendix Table A4, we show that our estimate of the conditional gender pay gap is robust to the inclusion of industry-by-year fixed effects, industry-by-title fixed effects, firm-by-year fixed effects, and firm-by-title fixed effects. The estimated gender gap across all these specifications ranges from 7.5 to 8.7%

pay gap, the conditional pay gap has continued to narrow throughout the entire time period, which could be an indication that the flattening out of the unconditional pay gap line is due to persistent gender gaps in promotion to higher-paying job titles.

Figure 4: Gender Pay Gap over Time

Notes: Gender gap in total compensation. The left panel reports the log of total compensation (in 2017 USD) for men and women separately, while the right panel reports the unconditional and conditional difference (conditional on experience, age, education, sales, markups, insider relationships, title fixed effects, and firm fixed effects).

5.2 Temporal Flexibility and Corporate Culture

Having established that women do end up in more flexible and female-friendly firms (see Figure 3), we now test whether this fact contributes to the gender pay gap. A compensating wage differential explanation predicts that firms that offer these amenities may pay less on average. To test this hypothesis we examine whether the estimated gender pay gap decreases after controlling for these amenities.

Column 1 of Table 5 reports the gender pay gap after controlling for executive characteristics, industry fixed effects, time-varying firm controls, and job title fixed effects. In column 2, we add our measures of female-friendly corporate culture and temporal flexibility. If compensating wage differentials are important, then the estimated gender gap in column 2 should be smaller. However, the estimated gap grows from 7% in column 1 to 8.8% in column 2. The coefficients on firm diversity and firm flexibility are positive and statistically significant, which means that diverse and

flexible firms tend to pay *more*, not less.²¹ When we control for firm fixed effects (in column 3), which account for all time-invariant firm-specific unobservables, there is a gender pay gap of 8%.²² In short, although women are selecting into more flexible and female-friendly firms, this sorting is not responsible for the gender pay gap that we document.

Table 5: Gender Compensation Gap By Firm Characteristics

	(1)	(2)	(3)	(4)

Indiv. Controls	Yes	Yes	Yes	Yes
Firm Controls	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes
Job Title FE	Yes	Yes	Yes	Yes
Firm FE	No	No	Yes	Yes

Notes: Standard errors (clustered at the industry level) in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Indiv. Controls are age (including a dummy for missing age), gender, and experience. firm controls are lagged sales, lagged markups, and insider relationships. Regressions restrict to firms with non-missing flexibility and corporate culture variables.

However, it is still possible that temporal flexibility and corporate culture could lead to gender pay gaps *within* firms. For example, a corporate culture that is competitive and male-dominated may favor men within a firm. Similarly, if women choose tasks within the firm that provide greater temporal flexibility but pay less, then gender pay gaps will be larger at flexible firms.

We first conduct a simple descriptive exercise to shed light on these hypotheses. In Figure 5, we

²¹While we are interpreting this as evidence against a standard compensating wage differential story, it is possible that compensating wage differentials are in play in the following way: women who value these amenities accept lower wages but end up becoming more productive due to the amenities and therefore earn higher annual compensation.

²²Note that this specification is identical to that of column 6 in Table 4, except here firms with missing culture and flexibility data are excluded.

illustrate average female compensation, average male compensation, and the difference between the two – separately for female CEO firms, diverse firms, flexible firms, and all other firms. Average compensation for both men and women is higher in female CEO firms, diverse firms, and flexible firms than other firms, consistent with the regression results in column 2 of Table 5. Importantly, we also find that gender gaps in compensation are smaller within female friendly and flexible firms. Specifically, we see in Figure 5 that the gender pay gap is larger at the "other" firms, which do not offer a female friendly corporate culture or temporal flexibility.

Figure 5: Compensation by Firm Type

Notes: Average female compensation, male compensation, and gender compensation gap at firms that have ever had a female CEO, at firms that promote diversity (non-zero diversity score), at firms that offer temporal flexibility (non-zero flexibility score), and all other firms.

To test this hypothesis more formally, we add interactions between the female indicator and our three firm characteristics in column 4 of Table 5 (as outlined in Equation 2). The significant positive coefficient on the first interaction term indicates that the gender gap falls by about half at firms that have ever had a female CEO. The next interaction term reveals a similar story – the gender pay gap is much smaller at firms that promote diversity. Scaling by the median diversity score among diverse firms (0.18), we find that gender pay gap is 3 percentage points smaller at the median diverse firm. The fact that the gender pay gap is significantly smaller at these female-friendly firms supports the idea that a male-dominated corporate culture is prevalent elsewhere and is contributing to the gender pay gap. On the other hand, there is no evidence that the gender pay

gap is larger at firms that offer temporal flexibility. The coefficient on the flexibility interaction term is negative but small in magnitude and statistically insignificant in column 4.²³

Similar to the entry and exit analysis, we also show that our results are robust to interacting the individual controls (age, experience, and job title) with our firm variables of interest, to interacting our female indicator with sales, markups, and board structure (column 5 of Table A3), and to dropping CEOs from the analysis (column 6 of Table A3). Our main conclusions remain unchanged.

To alleviate concerns about reverse causality and to maintain an adequate sample size, we prefer using these time-invariant firm-level measures. However, we also report results that use time-varying measures of corporate culture and flexibility in Table A5. Despite the loss of more than half the sample, the results are similar. The gender pay gap is significantly smaller at firms with a female-friendly corporate culture but not different at firms that offer temporal flexibility. We use these estimates to calculate how much of the observed decline in the conditional gender pay gap (Figure 4) can be explained by corporate culture. Specifically, a back of the envelope calculation multiplies the change in the Female CEO and Firm Diversity variables by their respective coefficients in column 5 of Table A5. We find that these two factors together explain 18% of the observed decline in the conditional gender pay gap.²⁴

Overall, these findings provide new insight into gender employment and compensation gaps at top executive positions. Although we show that female executives are selecting into firms with temporal flexibility and female-friendly corporate culture, there is no evidence that this affects gender pay gaps through a compensating wage differential story. Instead, there is evidence that these firm characteristics are related to gender pay gaps *within* the firm. Specifically, gender pay gaps are smaller at firms with female-friendly corporate cultures.

5.3 Compensation Type

This section explores whether the gender pay gap varies with the type of compensation. Discretionary pay is often more susceptible to the influence of negotiation and insider relationships which could disproportionately favor men (Biasi and Sarsons, 2020; Cullen and Perez-Truglia, 2019; Keller

²³Note that these regression results control for other potentially confounding individual, firm, and occupation characteristics, while Figure 5 does not.

²⁴While the point estimate on the Female CEO interaction term is larger, relatively few women become CEOs in our sample and thus the Firm Diversity variable plays a larger role in the decline in the conditional gender pay gap. Due to missing Firm Diversity data in 2017, this calculation is based on changes from 1992 to 2016.

and Olney, 2021).

Indiv. Controls	Yes	Yes	Yes	Yes	Yes	Yes
Firm Controls	Yes	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes	Yes	Yes
Job Title FE	Yes	Yes	Yes	Yes	Yes	Yes
Firm FE	Yes	Yes	Yes	Yes	Yes	Yes

Notes: Standard errors (clustered at the industry level) in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Individual controls are age (including a dummy for missing age), gender, and experience. firm controls are lagged sales, lagged markups, and insider relationships.

We test this prediction in Table 6, by reporting the conditional gender pay gap using salary and non-salary compensation as our dependent variables. The findings show that women earn 4.4% less in salary compared to their male colleagues (column 1) but 8.5% less in non-salary compensation (column 2). In the remaining columns, we report results for each component of non-salary compensation, including bonuses, stocks, options, and other compensation. Across all types of non-salary compensation (except compensation from stocks, which is the smallest component), the gender gap is larger than the gender gap in salary compensation.

The fact that the gender pay gap is larger for more discretionary forms of compensation is broadly consistent with our earlier findings showing that corporate culture is important. Specifically, corporate culture that favors men may be more likely to manifest itself in the form of discretionary compensation.

We explore these possibilities in more detail in Table 7, which replicates the specification in column 4 of Table 5 but uses different types of compensation as the dependent variable. Comparing the Female coefficient in columns 1 and 2, we again see that the gender pay gap is larger for non-salary compensation (coefficient of -0.16 in column 2 versus -0.07 in column 1). Importantly, however, the firm diversity interaction coefficients indicate that the gender gap in salary and non-salary compensation is smaller at female-friendly firms that promote diversity.²⁵

²⁵For example, the gender pay gap in non-salary compensation at the median diverse firm (with a score of 0.18) is

Table 7: Gender Gap by Compensation Type and Firm Characteristic

Notes: Standard errors (clustered at the industry level) in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Individuals controls are age (including a dummy for missing age), gender, and experience. firm controls are lagged sales, lagged markups, and insider relationships. Regressions restrict to firms with non-missing flexibility and corporate culture variables.

We then disaggregate non-salary compensation into bonuses, stocks, stock options, and other compensation. The negative female point estimate is largest for bonuses (column 3), but also sizable and statistically significant for stocks and other compensation (columns 4 and 6). The interaction coefficients show that the gender bonus gap shrinks substantially at firms that promote diversity, which is what we would expect to see if corporate culture is important. Conversely, the gender gaps in bonuses and stock options are larger at firms that offer temporal flexibility. This provides some evidence that women may take advantage of temporal flexibility but then receive less discretionary pay as a result.

6 Conclusion

This paper examines gender differences among top business executives. The results provide unique insight into one of the most high-stress, time-intensive, and competitive work environments. The findings highlight impediments to female employment and identify potential determinants of gender pay gaps, which may be of interest more broadly.

Over the last quarter century the female share of top business executives averaged 6%. Furthermore, the women that do work in this profession earn 8% less than otherwise similar male colleagues in the same positions. However, the share of female executives is increasing and the conditional gender pay gap is decreasing over our sample period.

We examine whether corporate culture and temporal flexibility can explain these features of this executive labor market. There is evidence that the female share of executives is higher at firms with more temporal flexibility (via higher female entry rates) and at firms with a more female-friendly culture (via lower female exit rates). While there is evidence that women select into firms with these amenities, our findings show that this does not lead to a gender pay gap, via a compensating wage differential story.

However, when looking at compensation differences *within* firms, we find that at female-friendly firms the gender pay gap is smaller, indicating that corporate culture is important. Finally we show that the gender pay gap is larger for discretionary pay, but again this gap shrinks at female-friendly firms.

only 9.6 percent (i.e. $-0.156 + 0.18 \times 0.336 = -0.096$).

There is a rich literature in economics – both experimental and observational – that examines gender differences in various characteristics and gender discrimination in various settings. This large body of work suggests some possible explanations for the large gender gaps in executive employment and pay, as well as the significantly smaller gaps at female-friendly firms.

Lower female representation and pay in top executive positions (even after controlling for observed characteristics) could be due to gender differences in a number of dimensions. For example, previous work shows that women tend to be less competitive (Buser, 2014; Croson and Gneezy, 2009; Niederle, 2016; Niederle and Vesterlund, 2007; Sutter and Glätzle-Rützler, 2015), less confident (Niederle and Vesterlund, 2007), are less likely to negotiate (Hernandez-Arenaz and Iriberri, 2019), and less likely to self promote (Exley and Kessler, 2019). This combination of differences could deter women from pursuing top management positions in the first place, make them less successful at obtaining these positions conditional on trying, and result in lower pay conditional on making it to the top.²⁶ Firm characteristics might moderate the outcome gaps generated by these gender differences. In particular, existing research suggests that women might behave differently in settings with more women (Chen and Houser, 2019; Hernandez-Arenaz and Iriberri, 2018), which could help explain why we find muted gender gaps in firms with female leadership.

It could also be the case that women experience discrimination in promotion and salary determination, as has been found to be the case in other male-dominated settings (Goldin and Rouse, 2000; Moss-Racusin et al., 2012). This kind of discrimination could be due to incorrect perceptions of female ability (Beg et al., 2021). If these inaccuracies are less common at female-friendly firms (which have had more exposure to female executives), this is another way through which corporate culture can affect the size of gender pay gaps.

Given that the executives we study are all in leadership roles, it is also important to note the growing evidence that women are evaluated differently in leadership roles (Ayalew et al., 2021; Brooks et al., 2014; Grossman et al., 2019). Importantly, evidence suggests these issues can be mitigated by greater exposure to female leaders (Beaman et al., 2009; Gangadharan et al., 2016). For these reasons, female leadership is one component of corporate culture that could be especially important in determining the size of a firm’s gender pay gap.

²⁶According to O*NET data, CEOs rank in the top three percentile of all jobs in terms of both competitiveness and negotiation.

In sum, the gender gaps we document in our setting could be driven by a combination of factors: gender differences in characteristics like competitiveness and negotiation, discrimination in promotion or salary determination, or differences in how male and female leaders are evaluated. Gaps generated by these differences could be mitigated by greater exposure to female leadership, which could explain why we find smaller gaps in female-friendly firms. Overall, these findings provide important lessons for policy makers who are interested in closing the remaining gender gaps in employment and compensation.

Notes: Standard errors (clustered at the industry level) in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Indiv. Controls are age (including a dummy for missing age), gender, and experience. Firm controls are lagged sales, lagged markups, and insider relationships. Additional interactions include: interactions between the female indicator and all firm controls, as well as interactions between each of the firm measures (female CEO, firm diversity, and firm flexibility) and all individual controls and job title indicators. Regressions restrict to firms with non-missing flexibility and corporate culture variables.

Table A4: Gender Compensation Gap with Additional Fixed Effects

	(1)	(2)	(3)	(4)	(5)	(6)
	Total Comp	Total Comp	Total Comp	Total Comp	Total Comp	Total Comp
Female	-0.079*** (0.009)	-0.079*** (0.009)	-0.080*** (0.009)	-0.087*** (0.009)	-0.075*** (0.009)	-0.082*** (0.008)
Observations	234425	234286	234415	233371	234329	233270
